

Description of the SimuBP function

Usage

```
SimuBP(bran=list(span, para, offd), mupr=c( $\mu_1, \mu_2$ ), n0=c( $y_0, x_0$ ), tp)
```

Arguments

bran: a list of 3 components `span`, `para`, and `offd`, determining the branching rule of cell proliferation.

bran\$span: a character string taking value from "fixed", "exp", "unif", and "gam", specifying the cell lifespan. In particular, `span="fixed"` corresponds to a Galton-Watson process (GWP), and `span="exp"` corresponds to a Markov branching process (MBP).

bran\$para: a vector or matrix specifying the parameters of the cell life distribution. For example, when `span="fixed"` and `para=c(l1, l2)`, the life spans of the wild-type and mutant cells in the resulting GWP are `l1` and `l2`, respectively; when `span="exp"` and `para=c(a1, a2)`, the rate parameters of the exponential distributed life times of the wild-type and mutant cells in the resulting MBP are `a1` and `a2`, respectively; when `span="unif"` or "gam", `para=cbind(c(a1, b1), c(a2, b2))` specifies the pair of parameters for the life time distributions of the wild-type and mutant cells, respectively.

bran\$offd: a vector `c(p0, p1, ...)` specifying the offspring distribution. For example, `offd=c(0, 0, 1)` corresponds to a binary-fission (Yule) process, `offd=c(0.5, 0, 0.5)` corresponds to a birth-death process with equal birth and death rates.

mupr: a vector `c(μ_1, μ_2)` specifying the forward and backward mutation probabilities.

n0: a vector `c(y_0, x_0)` specifying the number of wild-type and mutant cells at $t=0$.

tp: a scalar specifying the time of plating.

Value

A vector `c(z_t, x_t)` where z_t is the total number of viable cells at t_p , and x_t is the number of mutant cells at t_p .

Example(s)

In the simulation code "Simu_S1a.R", the input arguments were set to be:

```
para = c(1, 1)
offd = c(0, 0, 1)
bran = list(span="exp", para=para, offd=offd) # Specifies a
binary-fission MBP with exponential rate 1 for both wild-type and
mutant cell life distributions
mupr = c(2e-4, 0) # Specifies forward mutation probability 2e-4,
no backward mutations allowed
n0 = c(1, 0) # The cell population starts with 1 wild-type cell
tp = 11 # The time of plating is 11
```

Then in the double for-loop, the simulated data were generated by

```
data = SimuBP(bran, mupr, n0, tp)
```
